# What is an embedded system?

## Embedded system

From Wikipedia, the free encyclopedia

An **embedded system** is a computer system with a dedicated function within a larger mechanical or electrical system, often with [real-time computing](#) constraints.<sup>[1][2]</sup> It is *embedded* as part of a complete device often including hardware and mechanical parts. Embedded systems control many devices in common use today.<sup>[3]</sup> Ninety-eight percent of all [microprocessors](#) are manufactured as components of embedded systems.<sup>[4]</sup>

Examples of properties of typically embedded computers when compared with general-purpose counterparts are low power consumption, small size, rugged operating ranges, and low per-unit cost. This comes at the price of limited processing resources, which make them significantly more difficult to program and to interact with. However, by building intelligence mechanisms on top of the hardware, taking advantage of possible existing sensors and the existence of a network of embedded units, one can both optimally manage available resources at the unit and network levels as well as provide augmented functions, well beyond those available.<sup>[5]</sup> For example, intelligent techniques can be designed to manage power consumption of embedded systems.<sup>[6]</sup>

Picture of the internals of an [ADSL](#) modem/router, a modern example of an embedded system. Labelled parts include a [microprocessor](#) (4), [RAM](#) (6), and [flash memory](#) (7).

# Typical characteristics of an embedded system

Embedded systems often have one or more of the following features:

1. Reduced power consumption
2. Reduced size
3. Low cost per unit
4. High Reliability
5. Reduced (zero) need of maintenance

# Example: In-Vehicle Infotainment

# Hardware commoditization

- Thanks to Moore's law, embedded systems have now enough computing power to allow adaptation and reuse of complex software originally developed for servers and desktops
  - Networking stacks and protocols
  - User Interface frameworks
  - Open Source software
- With the economy of scale achieved by smartphones and other consumer devices, complex computer architectures have become affordable also for embedded systems
- On the other hand, developing dedicated, custom hardware and porting standard platform software requires a huge investment and becomes justified only for high volume productions

# Example: GENIVI Demo Platform

```
$ slccount gdp_ivi9_beta/workspace
```

Totals grouped by language (dominant language first):

| perl:   | 197439   | (0.33%)  |

...

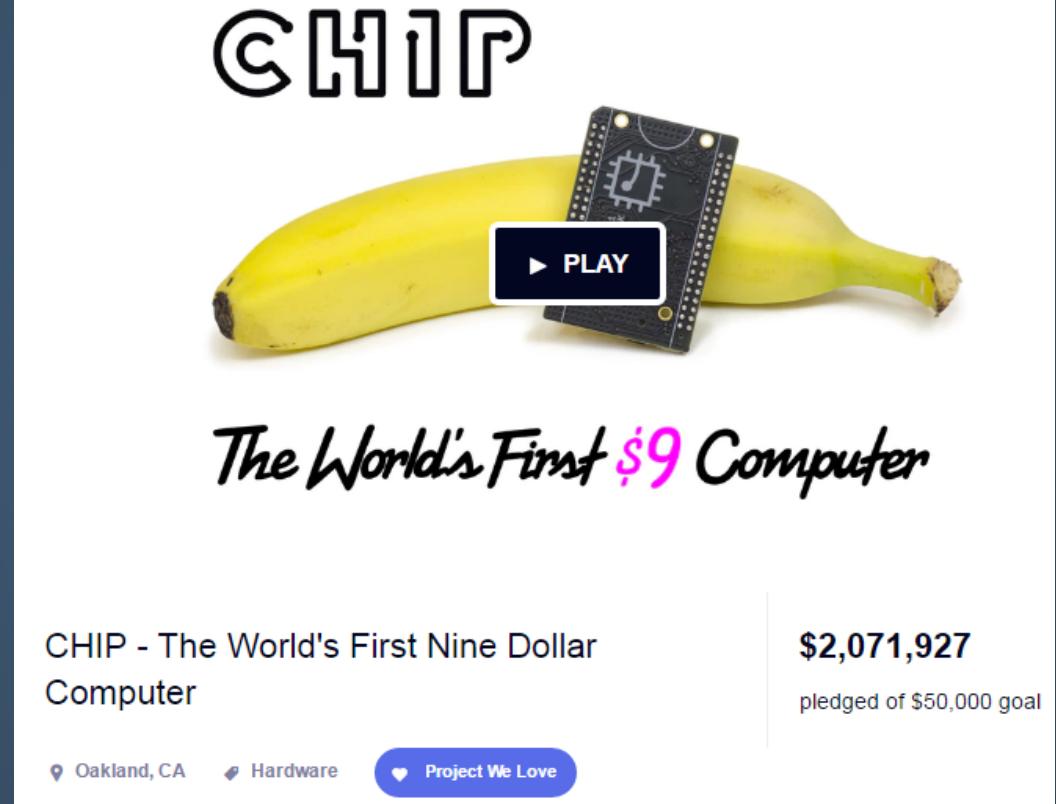

Total Physical Source Lines of Code (SLOC) = 59,405,160

# Standard HW/SW Platforms are becoming mainstream

- Low-cost building blocks to prototype embedded systems
- Complete with a ready-to-go Open Source software stack
- Widely used hardware interfaces
- Available for PoC and low-volume production
- Can speed up and reduce risk in embedded system design

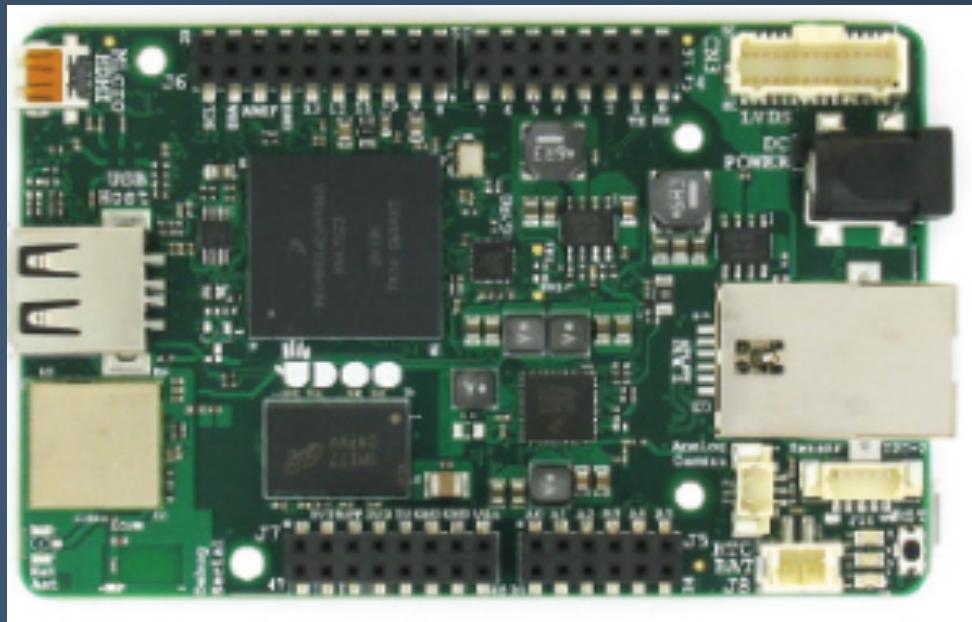

# CHIP - The World's First Nine Dollar Computer

- CPU: 1 GHz  
Allwinner A13
- GPU: Mali400
- RAM: 512 MB
- Flash: 4 GB
- WiFi  
802.11b/g/n
- Bluetooth 4.0
- OS: Debian

# UDOO NEO

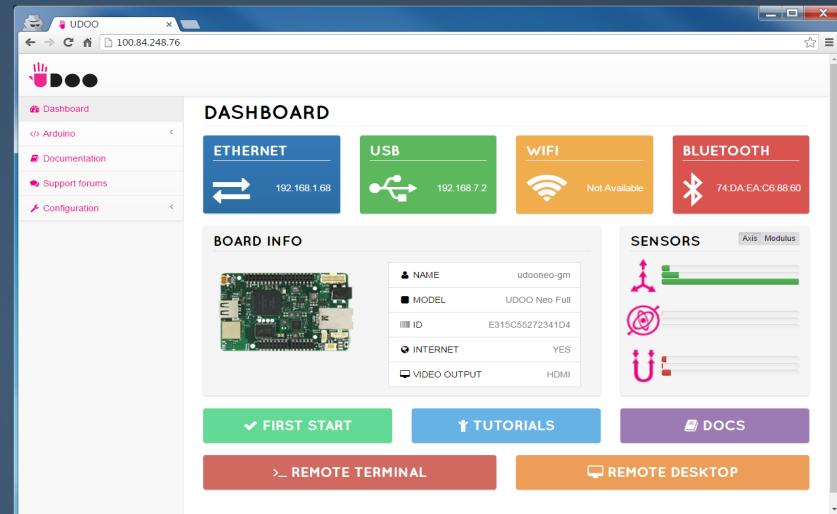

- CPU: Cortex A9
- MCU: Cortex M4
- RAM: Up to 1GB
- Integrated 2D/3D GPU
- Micro HDMI+LVDS
- Storage: MicroSD
- Audio: HDMI, S/PDIF
- USB: 1x2.0, 1xOTG
- Ethernet, WiFi, BT
- GPIO, Gyro, Accelerom,  
Magnetometer
- Arduino pinout

- OS: Android 5.1.1 /  
UDOOubuntu2 (14.04 LTS)
- Price: Starting from \$49.90

# UDOO Board Web Config

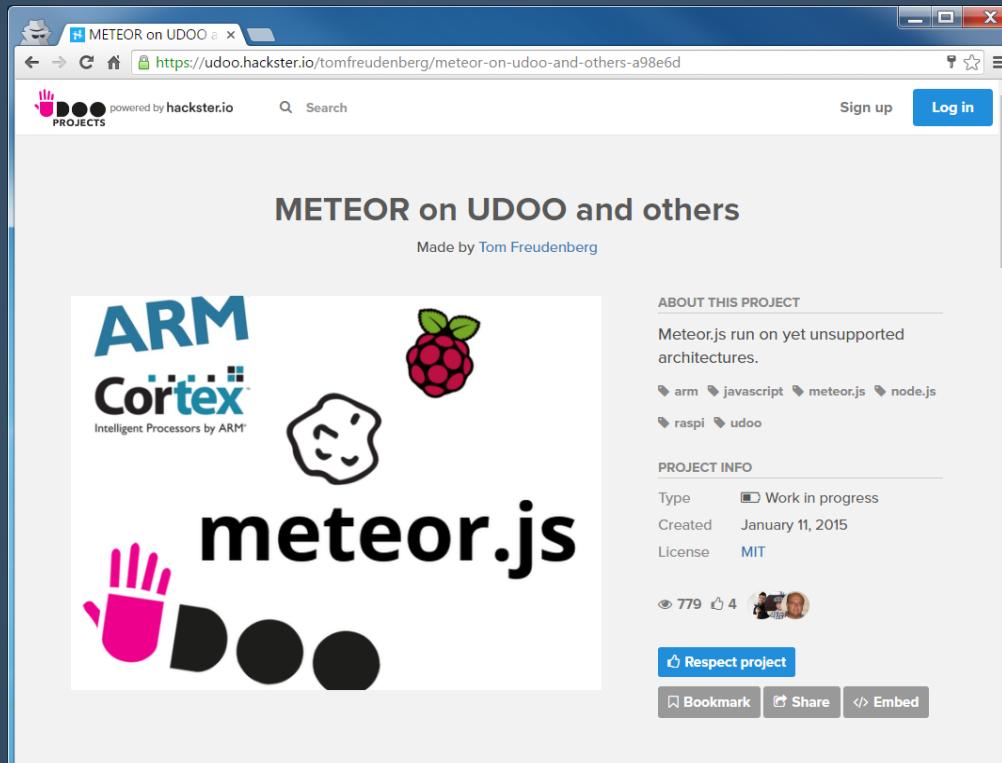

- Web-based application
  - Runs on the A9 core
- Features
  - Get board info
  - Read on-board sensors
  - Remote Terminal
  - Remote Desktop
  - Build Arduino sketches
  - Program M4 core
- Architecture: Node.js, Express 4, Socket.io
- Sources: <https://github.com/UDOOboard/udoo-web-conf>

# UDOO X86: The definition of "embedded system" is broadening...

The screenshot shows the Kickstarter campaign page for the UDOO X86. The title is "UDOO X86: The Most Powerful Maker Board Ever" by UDOO. The main image features the UDOO X86 board with its components and a "PLAY" button. Key specifications listed are Intel® Quad Core up to 2.56 GHz, up to 8GB RAM, 8GB eMMC, and Intel® Curie. The campaign has raised \$735,970 from 3,973 backers, starting from \$89. It has 4 days left. A green bar at the bottom indicates compatibility with Linux, Windows, Android, and Arduino. Below the main image, it states "10 times more powerful than Raspberry Pi 3, x86 64-bit architecture". Social sharing options are at the bottom left, and a bio section for UDOO is at the bottom right.

# Summary

- Embedded Systems: **more features, more capabilities**
  - HW is becoming a commodity unless for huge volumes
  - SW development and system validation becomes the issue
- Low-cost, standard HW platforms are now available - complete with a broad choice of Open Source software
  - Standard Web Frameworks and Tools are now affordable also on many types of embedded systems
- Relying on **proven and validated HW/SW platforms** allows embedded system developers to focus on application level and maximize the value to the end user
